

1. Performance Summary

Q1 Summary consists of a 3×3 table.

	Mu_T <dbl>	Sig_T <dbl>	SR_T <dbl>
Min	-1.24007798	0.09057667	-1.7884057
Mean	0.08582597	0.28297726	0.4968323
Max	1.19018268	1.01529441	3.8749416

Q2: Plot the asset mean returns against their volatilities

Q3(a): Report the relative performance measures in a 5×3 summary table

	Alpha	Beta	Tracking Error	Information Ratio	Treynor Ratio
Minimum	-0.0002000000	0.5205000	0.1825000	-0.28830000	-0.03490000
Meu	0.0001074074	0.9375519	0.2465667	-0.01945185	0.04856667
Maximum	0.0008000000	1.4540000	0.3669000	0.40860000	0.17430000

Q3(b): Best & Worst Stocks

Best: NKE relative high Treynor Ratio with low Tracking Error

Worst: CSCO, the stock has the lowest negative A negative ratio Treynor Ratio, indicates that the investment has performed worse than a risk free instrument.

Q4(a): Plot the mean return of each asset against its beta.

Q4(b): Plot JPM, GS, and AXP

2 Back-Testing

Q1

```
## [1] "SPY"
```

```

Q3.1

Q3.2

portfolio	beta	alpha	SR
<fctr>	<fctr>	<fctr>	<fctr>
portfolio1	0.979822688501692	-0.0924436090781786	3.98967722299554
portfolio2	1.12420177904119	-0.0583139690860298	6.29792561726823
portfolio3	1.01756812460256	-0.0409413400844204	3.85197803484115

3 rows

the 2-year cumulative return of portfolio 1 is 0.1175789

the 2-year cumulative return of portfolio 2 is 0.2184694

the 2-year cumulative return of portfolio 2 is 0.1173892

Q3.3

Portfolio 2 should be pick, since it has the largest cumulative return while the sharpe rate is big enough
Since each of three portfolio fails to “beat the market”, the EMH has been buttressed by this example

2

Another possible explanation is that since the Dow&Jones is constituted by large company, according to the ‘the small company effect’ In the behaviour finance, the return of Dow&Jones fails to beat the overall stock market which includes some small company

3 Random Numbers and Monte Carlo Simulation

Q1. Game 2 Phase 2:

The maximum amount I am willing to pay is 0.059, with 10^5 simulation times.

```
##{r}
N = 10^5
seq1 <- numeric()
for (n in 1:N) {
  c1 <- sample(1:6,6,TRUE)
  c2 <- (max(c1)-min(c1)) < 3
  seq1 <- c(seq1,c2)
}

round(mean(seq1),4)
##
```

[1] 0.059

Q2. Breaking Even:

The K value makes this game break-even is 0.2499388(is near 0.25), with 10^5 simulation times.

```
##{r}
seq3 <- numeric()
for (i in 1:10^5){
  seq2 <- numeric()
  while(sum(seq2)<2){
    seq2 <- c(seq2,sample(0:1,1))
  }
  time <- length(seq2)
  seq3 <- c(seq3,time)
}

100000/sum(seq3)
##
```

[1] 0.2499388

Q3. Pi

The idea to calculate pi value is based on the formula for calculating the area of circle:

when the radius of A is 1, the area of circle A is pi; therefore, the probability that one point (a,b), a,b are range from -1 to 1, located in the circle A, is equal to pi value.

```

f <- function(n){
  seq4 <- numeric()
  a <- runif(n,-1,1)
  b <- runif(n,-1,1)
  distance <- sqrt(a^2+b^2)
  I <- distance<1
  p <- 4*mean(I)

  library(ggplot2)
  f=seq(0,2*pi,0.001)
  x=sin(f)
  y=cos(f)
  plot(x,y,type='l',xlim=c(-1,1),ylim=c(-1,1),asp=1,col="black",lwd = 4)
  par(new=TRUE)
  plot(a,b,xlim=c(-1,1),ylim=c(-1,1),asp=1,col="orange",lwd=1)
  return (p)
}

f(8000)

```

The pi value is 3.146 with 8000 simulation times.

This chart is circle A, whose radius is 1, and 8000 simulation plots.

Q4

(a)

```

$$
E[Y_k] = E[X^k] = \int_{-1}^1 x^k dx = \frac{x^{k+1}}{k+1} \Big|_{-1}^1 = \frac{1}{k+1} \text{ if } k > -1
$$

```

$$E[Y_k] = E[X^k] = \int_{-1}^1 x^k dx = \frac{x^{k+1}}{k+1} \Big|_{-1}^1 = \frac{1}{k+1} \text{ if } k > -1$$

According to expression of the expected value of Y_k :

```

$$
V[Y_k] = E[Y_k^2] - E^2[Y_k] = E[X^{2k}] - E^2[X^k] = \frac{1}{2k+1} - \frac{1}{(k+1)^2} \text{ if } k > -1
$$

```

$$V[Y_k] = E[Y_k^2] - E^2[Y_k] = E[X^{2k}] - E^2[X^k] = \frac{1}{2k+1} - \frac{1}{(k+1)^2} \text{ if } k > -1$$

(b)

Because $E[Y_k]$ and $V[Y_k]$ are finite, $k \neq 1/2$ and $k > -1$, and because $V[Y_k] > 0$, $k \neq 0$.

(c)

```
Q <- function(k){
  X <- runif(10^5,0,1)
  Y <- X^k
  result <- c(mean(Y),var(Y))
  return (result)
}

C <- function(k){
  M <- (1-0^(k+1))/(k+1)
  V <- (1-0^(2*k+1))/(2*k+1)-((1-0^(k+1))/(k+1))^2
  return (c(M,V))
}

table <- data.frame(t(rbind(sapply(c(-10:10),Q),sapply(c(-10:10),C))),row.names = c(-10:10))
colnames(table) <- c("SE","SV","CE","CV")
table$K_value = c(-10:10)
table

ggplot(table, aes(x=K_value)) +
  geom_line(aes(y=SE, color="p1")) +
  geom_line(aes(y=SV, color="p2")) +
  geom_line(aes(y=CE, color="p3"))+
  geom_line(aes(y=CV, color="p4"))
```

SE,"SV","CE","CV" stand for simulate mean, simulate variance, calculated mean and calculated variance respectively. Get the following table and chart:

	SE <dbl>	SV <dbl>	CE <dbl>	CV <dbl>	K_value <int>
-10	2.908000e+44	8.456424e+93	Inf	NaN	-10
-9	1.211319e+53	1.467294e+111	Inf	NaN	-9
-8	3.032499e+33	3.566222e+71	Inf	NaN	-8
-7	1.198433e+28	9.267226e+60	Inf	NaN	-7
-6	6.638596e+22	4.388001e+50	Inf	NaN	-6
-5	1.014769e+23	1.029644e+51	Inf	NaN	-5
-4	9.810555e+12	3.617821e+30	Inf	NaN	-4
-3	6.691123e+10	4.014237e+26	Inf	NaN	-3
-2	1.119744e+05	1.884359e+14	Inf	NaN	-2
-1	1.151884e+01	1.810231e+05	NaN	NaN	-1

1-10 of 21 rows

Previous 1 2 3 Next

Since when K is range from -10 to -1, the calculated mean and calculated variance is infinite or NaN value, the lines in the chart are irregular.

(d)

Based on the restrictions of K value in (b), K is larger than -1 and not equal to 0, I draw a new chart:

From the above chart we can see that p1(simulated mean value) and p3(calculated mean value) overlap, p2(simulated variance value) and p4(calculated variance value) overlap, which means simulated values are nearly equal to calculated values.

Bonus:

First Let's look at simple case, if the required head number is 1 instead of 2:

Assume that we need to use expected n times to finish the simple game: then according to the first roll result, it satisfies the equation:

$$nk = \frac{1}{2} * k + \frac{1}{2}(n + 1)k$$

then, we have n = 2, which is the expected game times in simple the case.

Let's see the complex case when required head number is 2:

Again, assume that we need to use expected m times to finish the complex game: then according to the first roll result, if we success, we will enter the simple game, if we fails, we will return to the begin of complex game, which satisfies the equation:

$$mk = \frac{1}{2} * (1 + 2)k + \frac{1}{2} * (1 + m)k$$

then, the expected value of m is 4: then because mk=1, k=1/4

Notice here, k is not equal to $E[1/X]$, $k = 1/E[X]$, for example, if we play 100000 times game, the expected roll time is 400000, to make this total game fair, the expected value of k should be 1/4. Making every game fair and calculating average is a wrong method.

4 Value at Risk and Stress Testing

Task 1

Portfolio 1 -- GMV portfolio; Portfolio 2 -- Sharpe-ratio portfolio; Portfolio 3 -- naive portfolio

We refer to PerformanceAnalytics package by (Peterson and Carl 2018) to visualize the performance of the three portfolios.

```
chart.CumReturns(R_p, main = "Cumulative Return", legend.loc = "topleft")
```

Descriptive summary

	Portfolio_1	Portfolio_2	Portfolio_3
mean	0.1082536	0.2362662	0.1023947
std	0.1937506	0.2028444	0.2109120
SR	0.5587267	1.1647660	0.4854856

Question 1

To get started with the backtesting, we split the portfolio return into two periods in-sample (IN) and out-of-sample (OUT). Then estimate μ_i and σ_i using the IN to construct Portfolio 1, 2 and 3. After that, estimate the corresponding parameters from the OUT to demonstrate the sensitivity of each over time.

It appears that σ s exhibit a lower sensitivity than μ s, making the mean returns are more susceptible to model risk.

```
print(mean((M_in - M_out) ^ 2))
```

```
## [1] 0.05103022
```

```
print(mean((S_in - S_out) ^ 2))
```

```
## [1] 0.032454
```

Take a look on how the portfolio strategy performs

Mean and Standard deviation for p=1,2,3 using the daily returns in the OUT period:

	Portfolio_1	Portfolio_2	Portfolio_3
miu	0.0003058959	0.002083584	0.0002077179
sigma	0.0155675296	0.017153771	0.0173447471

Question 2

Simulated path of Geometric Brownian Motion

Portfolio 1 is a Global Minimum Variance portfolio which focuses on controlling the risk to the lowest, therefore which do have the lowest volatility but lack considerable rewards similar to portfolio 3 that simply equally distribute the funds. While Sharpe-ratio portfolio (p2) has a consideration on the risk-adjusted return of stocks allowing investors to have a bias on reward(highest mean) within undertaking a higher risk(highest variance).

Question 3

The expected value one year from now on is

	p1	p2	p3
expected value	83.77982	163.1078	127.7484

Question 4

With 95% level of confidence, the Value-at-Risk is

	p1	p2	p3
VaR	34.57601	37.77015	34.0068

Task 2

Referring to the SPY ETF as the markets, directly, we use the table.CAPM from the PerformanceAnalytics package to attain a number of statistics.

```
SPY <- get(getSymbols("SPY", from = "2017-01-01", to = "2020-09-30"))[, 6]
```

```
R_m <- na.omit(log(SPY / lag(SPY)))
```

```
names(R_m) <- "SPY"
```

```
table.CAPM(R_p_out, R_m)
```

VaR(0.05) for each portfolio is

	p1	p2	p3
VaR	3.014278	3.906139	3.149279

5 Mean-Variance Efficient Frontier

Q1. Plot the MVEF

Q2. Highlight SR & GMV points

Q3. Highlight EF & the economic rationale of theta

If $\theta > 1$, it means that we will short the SR portfolio and long the low risk portfolio. In other words, I will sell the SR portfolio despite not having the SR portfolio to get the money, and use the money and the principle to buy the low risk portfolio.

portfolio 2 is",
sum(portfolio2_Return), "\n" )
cat("the 2-year cumulative return of
portfolio 2 is",
sum(portfolio3_Return), "\n" )

```

Q3.3

```

Portfolio 2 should be pick, since it has the largest cumulative return while the sharpe rate is big enough

Since each of three portfolio fails to "beat the market", the EMH has been buttressed by this example

Another possible explanation is that since the Dow&Jones is constituted by large company, accroding to the 'the small company effect'

In the behaviour finance, the return of Dow&Jones fails to beat the overall stock market which includes some small company

# 3 Random Numbers and Monte Carlo Simulation

## Q1 Game2 Parse2

```
```{r echo=FALSE}
```

N=10^5

```
seq1 <- numeric() for(nin1:N){
```

I use 10^5 as the simulate times in this question.

```
## Q2 Breaking even ```{r
echo=FALSE} seq3 <- numeric()
for (i in 1:10^5){
```

```
seq2 <- numeric()
while(sum(seq2)<2){
```

```
seq2 <- c(seq2,sample(0:1,1)) }
```

```
time <- length(seq2)
```

```
seq3 <- c(seq3,time) }
```

```
100000/sum(seq3)
```

```
```
```

100000 is used as the simulate times in this question.

##Q3Pi

```
```{r echo=FALSE} f <-
function(n){
```

```
seq4 <- numeric()
```

```
a <- runif(n,-1,1)
```

```
b <- runif(n,-1,1)
```

```
distance <- sqrt(a^2+b^2) I <-
distance<1
```

```
p <- 4*mean(I)
```

```
library(ggplot2) f=seq(0,2*pi,0.001)
x=sin(f)
```

```
y=cos(f) plot(x,y,type='l',xlim=c(-
```

```
1,1),ylim=c(-
1,1),asp=1,col="black",lwd =2)
```

```
par(new=TRUE)
```

```
plot(a,b,xlim=c(-1,1),ylim=c(-
1,1),asp=1,col="orange",lwd=1)
```

```
return (p) }
```

```
f(1000)
```

```
```
```

In the chart, I plot a circle,whose radius is 1, to stand for pi value.

##Q4

### (a)

\$\$

$$E[Y_k] = E[X^k] = \int_0^1 x^k dx = \frac{x^{k+1}}{k+1} \Big|_0^1 =$$

```
c1 <- sample(1:6,6,TRUE) c2 <-
(max(c1)-min(c1)) < 3 seq1 <-
c(seq1,c2)
```

```
}
```

```
round(mean(seq1),4) ```
```

$$\frac{1}{k+1}, \text{ if } k \geq 1$$

\$\$

According to expression of the expected value of  $Y_k$ :

\$\$

$$V[Y_k] = E[Y_k^2] - E^2[Y_k] = E[X^{2k}] - E^2[X^k] = \frac{1}{2k+1} - \left(\frac{1}{k+1}\right)^2, \text{ if } k \geq -1$$

\$\$

### (b)

Because  $E[Y_k]$  and  $V[Y_k]$  are finite,  $k \neq -\frac{1}{2}$  and  $k > -1$ , and because  $V[Y_k] > 0$ ,  $k \neq 0$ .

### (c)

```
```{r echo=FALSE} Q <- function(k){
```

```
X <- runif(10^5,0,1)
```

```
Y <- X^k
```

```
result <- c(mean(Y),var(Y)) return(result)
```

```
}
```

```
C <- function(k){
```

```
M <- (1-0^(k+1))/(k+1)
```

```
V <- (1-0^(2*k+1))/(2*k+1)-
```

```
((1-0^(k+1))/(k+1))^2 return(c(M,V))
```

```
}
```

```
table <-
```

```
data.frame(t(rbind(sapply(c(-10:10),Q),sapply(c(-10:10),C))),row.names = c(-10:10))
```

```
colnames(table) <-
```

```
c("SE","SV","CE","CV")
table$K_value = c(-10:10)
```

```
table
```

```
ggplot(table, aes(x=K_value)) +
  geom_line(aes(y=SE,
```

```
color="p1")) +
```

```
geom_line(aes(y=SV,
```

```
color="p2")) +
```

```
geom_line(aes(y=CE,
```

```
color="p3"))+ geom_line(aes(y=CV,
```

```
color="p4")) geom_line(aes(y=CV,
```

```
```
```

SE","SV","CE","CV" stand for simulate mean, simulate variance, calculated mean and calculated variance respectively.

```
```{r echo=FALSE}
```

```
#remove 10 rows contain missing data:
```

```
table1 <-
```

```
data.frame(t(rbind(sapply(c(0:10),Q),sapply(c(0:10),C))),row.names = c(0:10))
```

```
colnames(table1) <-
```

```
c("SE","SV","CE","CV")
```

```
table1$K_value = c(0:10)
```

```
table1
```

```
ggplot(table1, aes(x=K_value)) +
  geom_line(aes(y=SE,
```

```
color="p1")) +
```

```
geom_line(aes(y=SV,
```

```
color="p2")) +
```

```
geom_line(aes(y=CE,
```

```
color="p3"))+ geom_line(aes(y=CV,
```

```
color="p4"))
```

```
```
```

When  $k \leq -1$ , the calculated mean value and variance are infinite, I draw a new picture, which doesn't contain missing data.

```
###(d)
```

```
```{r echo=FALSE}
```

```
table2 <-
```

```
data.frame(t(rbind(sapply(c(1:10),Q),sapply(c(1:10),C))),row.names = c(1:10))
```

```
colnames(table2) <-
```

```
c("SE","SV","CE","CV")
```

```
table2$K_value = c(1:10)
```

```
table2
```

```
ggplot(table2, aes(x=K_value)) +
  geom_line(aes(y=SE,
```

```
color="p1")) +
```

```
geom_line(aes(y=SV,
```

```
color="p2")) +
```

```
geom_line(aes(y=CE,
```

```
color="p3"))+
```

```
color="p4"))
```

```
```
```

Under the condition  $k > -1$  &  $K$  not equal to 0 from (b), from the above chart we can see that p1(simulate mean value) and p3(calculated mean value) overlap, p2(simulate variance value) and p4(calculated variance value) overlap, which means simulated values are nearly equal to calculated values.

## Bonus

First Let's look at simple case, if the required head number is 1 instead of 2:

Assume that we need to use expected  $n$  times to finish the simple game: then according to the first roll result, it satisfies the equation:

\$\$

$$nk = \frac{1}{2} * k + \frac{1}{2} (n+1)k$$

\$\$

then, we have  $n = 2$ , which is the expected game times in simple case.

Let's see the complex case when required head number is 2:

Again, assume that we need to use expected  $m$  times to finish the complex game: then according to the first roll result, if we success, we will enter the simple game, if we fails, we will return to the begin of complex game, which satisfies the equation:

\$\$

$$mk = \frac{1}{2} * (1+2)k + \frac{1}{2} * (1+m)k$$

\$\$

then, the expected value of  $m$  is 4: then because  $mk = 1$  \$to\$  $k = \frac{1}{4}$  \$.

Notice here,  $k \neq E[1/X]$ ,  $k = 1/E[X]$ , for example, if we play 100000 times game, the expected roll time is 400000, to make this total game fair, the expected value of  $k$  should be  $\frac{1}{4}$  \$. Making every game fair and calculating average is a wrong method.

## Task 1
```

```
### 1. Calibrate the price path for
each portfolio
```

Before implementing, we take a brief review on the three portfolio.

The weight allocated to asset i in Portfolio 1 is given by

$$\omega_i = \frac{\frac{1}{\sigma_i^2}}{\sum_{j=1}^d \frac{1}{\sigma_j^2}}$$

\$\$

where σ_i is the volatility of asset i for all $i = 1, \dots, 27$ and $\sum_{i=1}^{27} \omega_i = 1$. On the other hand, the weight allocated to asset i in

Portfolio 2 is

$$\omega_i^{SR} = \frac{SR_i}{\sum_{j=1}^{27} SR_j}$$

where SR_i denotes the SR of stock i for all $i = 1, \dots, 27$ and $\sum_{i=1}^{27} \omega_i^{SR} = 1$.

Portfolio 3 allocates equal weights to each asset such that

$$\omega_i^N = \frac{1}{27}$$

```
```{r echo=FALSE}
```

```
#portfolio return
```

$$W1 = (1 / (df$S^2)) / \sum (1 / (df$S^2))$$

$$W2 = df$SR / \sum(df$SR)$$

$$W3 = W2 / W2 * 1 / 27$$

```
names(W1) <- names(W2) <-
names(W3) <- names(R)
```

```

R_p1 <- as.matrix(R) %*% W1
R_p2 <- as.matrix(R) %*% W2
R_p3 <- as.matrix(R) %*% W3

#reformat back to xts and merge
together

R_p <- merge(R_p1, R_p2, R_p3)
```

We refer to PerformanceAnalytics package by (Peterson and Carl 2018) to visualize the performance of the three portfolio.

```

```{r echo=FALSE}
chart.CumReturns(R_p, main =
"Cumulative Return", legend.loc =
"topleft")
```

```{r echo=FALSE}
chart.Drawdown(R_p, main =
"Drawdown")
```

Descriptive summary

```

```{r echo=FALSE} my.sum =
function(x){

Mean = mean(x)

Std = sd(x)

SR = sqrt(252) * Mean / Std M <-
rbind(Mean * 252, Std

* sqrt(252), SR) return(M)

}

run over each column

```

```

```

```

sum.i <- apply(R_p, 2, my.sum)
rownames(sum.i) <- c("mean",
"std", "SR")

sum.i

```

To get started with the backtesting, we split the sample into two periods in-sample (IN) and out-of-sample (OUT).

```

```{r echo=FALSE} # backtesting

#separate

in_index <- 1:floor(0.5 * nrow(R))
R_in <- R[in_index, ]

R_out <- R[(max(in_index) +
1):nrow(R), ]

tail(R_in,2)

head(R_out,2)

```

Then estimate μ_i and σ_i using the IN to construct Portfolio 1, 2 and 3. After that, estimate the corresponding the parameters from the OUT to demonstrate the sensitivity of each over time. ```{r echo=FALSE}

#compute M and S using the in-sample

M_in <- apply(R_in, 2, mean) * 250

S_in <- apply(R_in, 2, sd) *
sqrt(250)

#compute M and S using the out-sample

M_out <- apply(R_out, 2, mean) *
250

S_out <- apply(R_out, 2, sd) *
sqrt(250)

```

```

```

plot(M_out ~ M_in,

ylab = "Out",

xlab = "In",

main = "Mean Returns")

abline(a=0,b=1,lty= "dashed")

plot(S_out ~ S_in, ylab = "Out",

xlab = "In",

main = "Volatility")
abline(a=0,b=1,lty= "dashed")

```

It appears that σ_i exhibit a lower sensitivity than μ_i , making the mean returns are more susceptible to model risk. ```{r echo=FALSE} print(mean((M_in - M_out) ^ 2)) print(mean((S_in - S_out) ^ 2)) ```

Take a look on how the portfolio strategy performs on OUT

```

```{r echo=FALSE}

```
```
```

<br>

Portfolio 1 is a Global

Minimum Variance portfolio which  
focus on controlling the risk to the  
lowest, therefore which do have the  
lowest volatility but lack  
considerable rewards similar to  
portfolio 3 that simply equally  
distribute the funds. While  
Sharp-ratio portfolio (p2) has a  
consideration on the risk- adjusted  
return of stocks allowing investors  
to have a bias on reward(highest  
mean) within undertaking a higher  
risk(highest variance).

<br>

### 3. Expected value of each  
portfolio one year from now The

expected value one year from now  
on is

```
```{r echo=FALSE}
```

#expected value

```
exp = cbind(p1 =

## Task 2

Referring to the SPY ETF as the  
markets, directly, we use the  
table.CAPM from the  
PerformanceAnalytics package to  
attain a number of statistics. ```{r  
echo=FALSE}

```
SPY <-
```

```
get(getSymbols("SPY", from =
"2017-01-01", to = "2020-09-
30"))[, 6]
```

```
R_m <- na.omit(log(SPY /
lag(SPY)))
```

```
names(R_m) <- "SPY"
```

```
table.CAPM(R_p_out, R_m)
table.Stats(R_p_out)
```

```
```
```

VaR(0.05) for each portfolio is ```{r
echo=FALSE}

```
sig_m = apply(R_p, 2, sd)
```

```
sig = apply(R_p_out, 2, sd) +  
data.frame(table.CAPM(R_p_out,  
R_m))["Beta", ]*sig_m * 0.1 sim11  
= gbm_path(N, m[1],  
as.numeric(sig[1]), 1, S)
```

```
sim22 = gbm_path(N, m[2],  
as.numeric(sig[2]), 1, S)
```

```
sim33 = gbm_path(N, m[3],  
as.numeric(sig[3]), 1, S)
```

```
VaR11 <- mean(sim11) -  
quantile(sim11, 0.05)
```

```
VaR22 <- mean(sim22) -  
quantile(sim22, 0.05)
```

```

(b) Economic rationale

If $\theta > 1$, it means that we will short the SR portfolio and long the low risk portfolio. In other words, I will sell the SR portfolio despite not having the SR portfolio to get the money, and use the money and the principle to buy the low risk portfolio.
